# **Alpine Rhine Decolmation Experiment**

Christian Gmünder, Simultec AG, Zürich

12-09-2024

## Motivation

#### Flood protection project at the Alpine Rhine

- To protect the densely populated valley from flooding, the Rhine channel will be widened
- 24 drinking water wells must be temporarily taken out of operation during construction works
- Due to the expected higher bed permeability, drainage channels will be constructed on both sides of the Rhine

12-09-2024

IAH 2024 World Groundwater Congress

## **Questions to answer**

- How much will the riverbed permeability increase during construction?
- Will the quality of the infiltrating groundwater change?
- How long will it take to colmatise the riverbed again?
- How long will it take until groundwater quality is good enough again?

# **Test site evaluation**

#### Site requirements

- Representative for existing drinking water catchments
- High permeable aquifer
- Heavily colmated Rhine bed
- Infiltration zone (all season)
- No risk for drinking water wells

Experimental setup

# **Experimental setup**

#### Pumping well

force the flow direction to slightly inwards

#### Monitoring wells

- along the riverbank
- perpendicular to the riverbank
- In two depth levels
- Intervention wells
- prevent high ground-water levels
  Excavation
- Area: 15 x 150 m
- Depth: 1 m

Experimental setup

# **Test Period**

- No heavy rainfall before and after excavation
- Rhine discharge low and constant

12-09-2024

### **Groundwater table rise**

Observations

12-09-2024

## **Groundwater model**

Regional model

 Calibrated to get good boundary conditions

## Magnifier model

- Embedded in the regional model
- Automatic calibration of the Rhine leakage with PEST
- Calibration parameters are the daily values of the Rhine leakage in the excavation area

12-09-2024

Test interpretation

# **Calibration method**

#### High time demand

- 441 parameter
- Direct calibration would need
  20 days of calculation time

## Solution: Time loop

- 10 time segments
- Small overlap
- 2 days of calculation time

## **Calibration results**

## Comments

- Mean error was 4 cm over the whole period (3034 measurements)
- Decolmation area is less than 1% of the Rhine area inside the model
- Errors in the remaining area must be compensated by the decolmation area
- $\rightarrow$  estimated uncertainty

12-09-2024

## **Flow direction**

- Flow direction changes from nearly parallel to nearly perpendiculat to the Rhine

## Sensitivity analysis of the resulting leakage value

#### Increase

- Sensitive, factor 200

#### Decrease

- Sensitive, exponential, 4%, later 2% daily decrease

# Remaining value

Not sensitive, factor 5 - 20

12-09-2024

### **Natural tracers: Radon**

- No <sup>222</sup>Rn in the Rine, half-live time of the saturation: 3.8 days
- Resulting flow-effective porosity: 10%

Test interpretation

IAH 2024 World Groundwater Congress

## Natural tracers: electrical conductivity

- Useful to distinguish between landside and riverside flow direction
- Saturation process unknown hypothesis needed

#### Hypothesis

- Background value 800 µS/cm
- Saturation by passing rock matrix up to 450 µS/cm with half-time of 100 days

Test interpretation

IAH 2024 World Groundwater Congress

## Natural tracers: oxygen concentration

- High oxygene values remain until today

### Hypothesis Nr. 8

- The high values are due to the remaining higher permeability in the excavation area
- The biofilm may have a restricted capacity to reduce oxygene
- Only parameter introduced: reduction capacity

#### Results

- Not so nice but simpler
- Must be combined with other effects (layered aquifer, mixing with immobile water)
